Abstract

TODO - "Short summary of the paper, including results. Often written last".

1 Introduction

1.1 Copy-Move Forgery Detection

Copy-Move Forgery is a class of image forgery where regions of an image are duplicated and moved to other areas of the image. Commonly, techniques such as rotation, flipping and scaling of the copied region are applied, as well as post-processing such as edge smoothing, brightness adjustment and adding extra noise. These techniques can lead to forgeries which are hard to detect both through manual review and automated detectors. This method of forgery can be used within scientific images in order to fabricate results, where the complexity of the figures creates additional difficulties. [1]

1.2 Related works

TODO: What have others tried to solve this problem? Are there similar problems studied?

1.3 Objectives

TODO

We aimed to create a full pipeline for CMFD which could perform well on the Recod.ai Scientific Image Forgery Detection dataset.

1.4 Contributions

TODO: What can the reader learn from this paper?

2 Methods

TODO: What did we do? Reader should be able to reproduce results.

Basically, detailed breakdown of final implementation goes here.

3 Results

TODO: Show results of experiments. NB: Without interpretation at this stage! Align with method section.

4 Discussion

TODO: Interpret results Relate to objectives (did we achieve them?) Compare against others (kaggle leaderboard?)
